review time per sample but also enables the pathologist to review samples remotely." SigTuple is also working on other products that will automate microscopy for other samples such as biopsies and pap smears.

In May this year, the Delhi-headquartered Dr Dangs Lab introduced Allergynius Dx, an advanced molecular allergy diagnostics test utilising cutting-edge microarray technology and nanoparticles. Priced at about Rs 25,000, this test can accurately detect potential allergies to 163 common allergens and analyse 300 components of various allergens. Eighteen-year-old Naman Maheshwari, a first-year college student from Delhi, took the test and says it has changed his life. Maheshwari had an allergic reaction to raw milk cheese as a child and had given up on milk altogether. But the test showed that the specific component of milk that triggered his allergy becomes denatured through heat or, in other words, is rendered inactive during cooking. "My doctor said I could safely have milk-based products that are cooked, but not raw milk. Recently, I savoured my first bowl of oatmeal cooked in milk and experienced no adverse reactions," says Maheshwari. According to Dr Arjun Dang, CEO of Dr Dangs Lab, there is a significant gap in precise allergy diagnosis in India. "With the introduction of Allergynius Dx, powered by AI, we aim to bridge this gap," he says. The test, he says, has "revolutionised the field of allergy diagnostics", as by identifying the exact triggers responsible for allergic reactions, healthcare professionals can now offer tailor-made treatment plans and personalised recommendations to patients.

HOW PREDICTIVE ANALYTICS WORKS

Predictive analytics basically works on historical data, comparing a patient's test results with an entire database of similar reports, research and parameters. Of course, for accuracy and level of confidence in the final diagnosis, a lot depends upon the backend data provided to the AI-powered machine. "You need to train an algorithm on
