pressure gradient force is balanced by the Coriolis force and the resultant wind blows parallel to the isobar. This wind is known as the geostrophic wind.

The wind movement around a low is called cyclonic circulation. Around a high it is called anti cyclonic circulation. The direction of winds around such systems changes according to their location in different hemispheres.

Difficulty Level: Tough

71. The pattern of planetary winds depend on:
    1. latitudinal variation of atmospheric heating;
    2. emergence of pressure belts;
    3. the migration of belts following apparent path of the sun;
    4. the distribution of continents and oceans;
    5. the rotation of earth (Coriolis force).

    The pattern of the movement of the planetary winds is called the general circulation of the atmosphere. The general circulation of the atmosphere also sets in motion the ocean water circulation which influences the earth's climate.
72. **Statement 1: CORRECT**—The trade winds are those blowing from the sub-tropical high pressure areas towards the equatorial low pressure belt. Therefore, these are confined to a region between 30°N and 30°S throughout the earth's surface.

    Statement 2: INCORRECT—Trade winds are descending and stable in areas of their origin (subtropical high pressure belt), and
