as they reach the equator, they become humid and warmer after picking up moisture on their way.

Statement 3: CORRECT—The eastern parts of the trade winds associated with the cool ocean currents are drier and more stable than the western parts of the ocean.

73. **Statement 1: CORRECT**—The westerlies are the winds blowing from the sub-tropical high pressure belts towards the sub polar low pressure belts.

They blow from southwest to north-east in the northern hemisphere and north-west to south-east in the southern hemisphere.

Statement 2: INCORRECT—The westerlies of the southern hemisphere are stronger and persistent due to the vast expanse of water, while those of the northern hemisphere are irregular because of uneven relief of vast land-masses.

Statement 3: CORRECT—Western Disturbance plays important role in bringing moderate to heavy rain in low-lying areas and heavy snow to mountainous areas of the Indian Subcontinent especially in winter. This disturbance is usually associated with cloudy sky, higher night temperatures and unusual rain.

74. **Statement 1: INCORRECT**—Easterly trade winds helps ingetting rains over India during both Southwest and North-east monsoons.

Statement 2: CORRECT—Monsoons were traditionally explained as land and sea breezes on a large scale. Thus, they were considered a convectional circulation on a giant scale.

The monsoons are characterised by seasonal reversal of wind direction.

75. *Valley Breeze and Mountain Breeze:* In mountainous regions, during the day the slopes get heated up and air moves upslope and to fill the resulting gap the air from the valley blows up the valley. This wind is known as the **valley breeze**.

During the night the slopes get cooled and the dense air descends into the valley as the mountain wind (Mountain Breeze). The cool air, of the high plateaus and ice fields draining into the valley is called **katabatic wind**.

Another type of warm wind (katabatic wind) occurs on the leeward side of the mountain ranges. The moisture in these winds, while
