1. Cold currents bring cold water into warm water areas [from high latitudes to low latitudes]. These currents are usually found on the west coast of the continents in the low and middle latitudes (true in both hemispheres) and on the east coast in the higher latitudes in the Northern Hemisphere;
2. Warm currents bring warm water into cold water areas[low to high latitudes] and are usually observed on the east coast of continents in the low and middle latitudes (true in both hemispheres). In the northern hemisphere they are found on the west coasts of continents in high latitudes.

35. **Statement 1 and 2: CORRECT—**
See Explanation Fig. on the next page
Statement 3: INCORRECT—Counter-equatorial current flows between the north equatorial current and the south equatorial current in west-east direction.

36. Winter Circulation
- Under the influence of prevailing trade winds [easterly trade winds], the north equatorial current and the south equatorial current start from the south of Indonesian islands, moving from east to west.
- This raises the level of western Indian (south-east of horn of Africa) ocean by few centimeters. And this creates a counter-equatorial current which flows between the north equatorial current and the south equatorial current in west-east direction.
- The north-east monsoons drive the water along the coast of Bay of Bengal to circulate in an anticlockwise direction.
- Similarly, the water along the coast of Arabian Sea also circulate in an anti-clockwise circulation.

37. **How does deep water marine organisms survive in spite of absence of sunlight?**
- Photic zone is only about few hundred meters. It depends on a variety of factors like **turbidity**, presence of algae, etc.
- There are no enough primary producers below few hundred meters till the ocean bottom.
- At the sea bottom, there are bacteria that make use of heat supplied by earth's interior to prepare food. So, they are the primary producers.
