Explanation (35)

- Other organisms feed on these primary producers and subsequent secondary producers.
- So, the heat from earth supports wide ranging deep water marine organisms.

38. Statement 1: CORRECT—The process of heating and cooling of the oceanic water is slower than land due to vertical and horizontal mixing and high specific heat of water.

Statement 2: INCORRECT—

The ocean water is heated by three processes.

1. Absorption of sun's radiation.
2. The conventional currents: Since the temperature of the earth increases with increasing depth, the ocean water at great depths is heated faster than the upper water layers. So, convectional oceanic circulations develop causing circulation of heat in water.
3. Heat is produced due to friction caused by the surface wind and the tidal currents which increase stress on the water body.

Statement 3: CORRECT—

The ocean water is cooled by
