33. Chlorinated Hydrocarbons (CHCs)
    - CHCs are hydrocarbons in which one or more hydrogen atoms have been replaced by chlorine e.g. DDT (dichlorodiphenyltrichloroethane), endosulfan, chloroform, carbon tetrachloride, etc.
    - DDT accumulated in food chains and caused eggshell thinning in certain bird species.
    - In India, it is still being used by civic administrations as a mosquito repellent (disease vector control).
    - DDT residues continue to be found in mammals all across the planet. In Arctic areas, particularly high levels are found in marine mammals.
    - Because of its threats to human health and the environment, a global ban on the manufacture and use of endosulfan was negotiated under the Stockholm Convention in 2011.
34. Podzols
    - Podzols are the typical soils of a coniferous or boreal biome.
    - The top layer of the soil is very thin and is overlain over sandy or loamy subsurface which has no organic matter (lost due to leaching of nutrients to the bottom layers).
    - The soils are characterised by low levels of moisture (excessively drained) and nutrients and are loamy or sandy. Others have shallow rooting zones and poor drainage due to subsoil cementation.
    - A low pH further compounds issue. The low pH (acidic) is due to excessive leaching of alkaline matter which if present would neutralise the organic acids of the accumulating litter.
    - Hence, most Podzols are poor soils for agriculture. They are mostly used for grazing.
35.
    - Sub-Tropical Deciduous Biome- Eastern China, South Eastern USA
    - Temperate Deciduous Biome (North-Western Europe-British Type Climate)-England
    - Temperate Rainforest Biome
    - This is a small biome in terms of area covered. The main stretch of this habitat is along the north western coast of North America
