

29. Statement 1: CORRECT—The North American tundra has temperature rises above freezing for a short period every summer. Statement 2: CORRECT—The Pacific Northwest area has the highest average rainfall in North America.
30. Tropical air spreads north in February and dominates the region until November, when polar continental air occasionally invades. Winters are mild, with January means of 40 to 54°F (4 to 12°C). July averages are tropical, with highs exceeding 80°F (28°C). The warmth and the long growing season allow subtropical crops such as cotton and peanuts (groundnuts) to be grown. Rainfall is ample (40 to 60 inches [1000 to 1500 mm]) and benefits from the presence of the Colorado and Texas low-pressure systems and from thunderstorms that flare up on warm afternoons in the tropical maritime air. Since the landmass is intensely heated, frequent thunderstorms dot the landscape in this region, especially in early summer. Hurricanes are an annual hazard along the Gulf of Mexico and up the lower Mississippi valley.
31. In the American Southwest a Mediterranean type of climate is found. Summers are dry there, because tropical continental air is dominant. July with 70 to 80°F (21 to 27°C) are typical, with bright, sunny skies. Winters are mild (45 to 50°F [7 to 10°C]) and somewhat wet, with polar Pacific airs swinging south and bringing occasional heavy rain. Frost and snowfall are rare but may occur when polar continental air thrusts through to the coast. Los Angeles has a record low temperature of only 23°F (- 5°C). Annual
