35. **Northwest cloudbands** bring rain to much of northwestern, central and southeastern Australia.

What are they?

A northwest cloudband is an extensive layer of cloud which can stretch from northwest to southeast Australia.

Northwest cloudbands are formed when warm, moist tropical air originating over the Indian Ocean moves poleward (generally southeastward), and is forced to rise over colder air in the mid-latitudes. This typically occurs when tropical air to the northwest of Australia moves poleward on the western flank of a high pressure system over eastern Australia.

Northwest cloudbands can also interact with cold fronts and cut-off lows over southeastern Australia to produce very heavy rainfall.

Northwest cloudbands may have links with the Indian Ocean Dipole. When Indian Ocean sea surface temperatures to the northwest of Australia are warmer than average, northwest cloudbands may become more frequent and produce heavier rainfall.

36. Tanami desert- Great sandy desert- Gibson desert- Great Victoria desert.

(See Figure on next page)

37. All cities lies on eastern Australia.

From south to north: Melbourne-Canberra-Sydney- Brisbane

(See Figure on page no. 193)

38. All ranges lies on southern Australia

From west to east: Darling Ranges- Flinders RangesBarrier Ranges- New England Ranges
