3. The paragraph explains earthquake. Earthquake and Volcanism are diastrophic movements of Earth. Tsunami is a result of Earthquake under oceanic crust. Orogenic processes are mountain building processes.
4. Earthquakes may cause change in contours, change in river courses, ‘tsunamis’ (seismic waves created in sea by an earthquake, as they are called in Japan) which may cause shoreline changes, spectacular glacial surges (as in Alaska), landslides, soil creeps, mass wasting etc.
5. Denudation mainly depends on rock type and its structure that includes folds, faults, orientation and inclination of beds, presence or absence of joints, bedding planes, hardness or softness of constituent minerals, chemical susceptibility of mineral constituents; the permeability or impermeability etc.
6. Physical or mechanical weathering processes depend on some applied forces like (i) gravitational forces (ii) expansion forces due to temperature changes, crystal growth or animal activity; (iii) water pressures controlled by wetting and drying cycles.
7. Salts in rocks expand due to thermal action, hydration and crystallisation. Many salts like calcium, sodium, magnesium, potassium and barium tends to expand. High temperature ranges in deserts favour such salt expansion. Salt crystals in near-surface pores cause splitting of individual grains within rocks, which eventually fall off. This process of falling off individual grains may result in granular disintegration or granular foliation.
8. Significance of weathering
   - Weathering is the first step in formation of soils.
   - Weathering of rocks and deposits helps in the enrichment and concentrations of certain valuable ores of iron, manganese, aluminium, copper etc. Without weathering, the concentration of the same valuable material may not be economically viable to exploit, process and refine. This is what is called enrichment.
   - Weathering helps in soil enrichment.
9.
