Peninsular rivers except Narmada and Tapi flow from west to east.

60. The Brahmaputra, one of the largest rivers of the world, has its origin in the Chemayungdung glacier of the Kailash range near the Mansarovar lake. From here, it traverses eastward longitudinally for a distance of nearly 1,200 km in a dry and flat region of southern Tibet, where it is known as the Tsangpo, which means 'the purifier.' The Rango Tsangpo is the major right bank tributary of this river in Tibet.

Difficulty Level: Tough

61. A galaxy starts to form by accumulation of hydrogen gas in the form of a very large cloud called *nebula*. Eventually, growing nebula develops localised lumps of gas. These clumps continue to grow into even denser gaseous bodies, giving rise to formation of stars.

    The formation of stars is believed to have taken place some 5-6 billion years ago.

62. The Big Bang theory by Alexander friedman is a cosmological model for the observable universe from the earliest known periods through its subsequent large-scale evolution. The model describes how the universe expanded from a very high-density and high-temperature state.

    Steady state theory is opposite to the Hubble's expanding universe theory. It states that the objects in the universe stay still and steady. Though the universe expands it maintains a constant average density nebular hypothesis states that the planets were formed out of a cloud of material associated with a youthful sun, which was slowly rotating.

63. The stars are localised lumps of gas within a nebula. The gravitational force within the lumps leads to the formation of a core to the gas cloud and a huge rotating disc of gas and dust develops around the gas core.

    In the next stage, the gas cloud starts getting condensed and the matter around the core develops into small rounded objects. These small-rounded objects by the process of cohesion develop
