Glacial Depositional Landforms

- Outwash Plain
- Esker
- Kame Terraces
- Drumlin
- Kettle Holes
- Moraine

17. All except Cirque are fluvial depositional landforms. Cirque is a glacial deposit landform.
18. A tsunami which was imperceptible in deep water may grow to many metres high and this is called the ‘shoaling’ effect. Rest of the options are various aspects of fluvial erosion.
    - Corrasion or abrasion is solid river load striking against rocks and wearing them down.
    - Hydration occurs due to force of running water wearing down rocks.
    - Attrition is river load particles striking, colliding against each other and breaking down in the process.
    - Downcutting is erosion in vertical direction (downcutting leads to valley deepening) or
    - Lateral erosion is erosion in horizontal direction, especially the walls of the stream.
    - Corrosion is the chemical action that leads to weathering.
19. Terraces are stepped benches along the river course in a flood plain.

    Gulley is an incised water-worn channel, which is particularly common in semi-arid areas.

    A meander is defined as a pronounced curve or loop in the course of a river channel.

    Sill is a volcanic landform in form of tabular sheet intrusion caused by volcanic lava.
