With the introduction of green revolution technologies, the modern agriculture has become all the more dependent upon the steady supply of synthetic inputs, such as fertilisers, which are products of fossil fuel, i. e., coal and petroleum. Due to the excessive and imbalanced use of these synthetic inputs, adverse effects are being noticed.

7. Organic farming is a form of agriculture that relies on crop rotation, green manure, compost, biological pest control, and mechanical cultivation to maintain soil productivity and control pests, excluding or strictly limiting the use of synthetic fertilisers and synthetic pesticides, plant growth regulators, livestock feed additives, and genetically modified organisms.

   The term holistic is often used to describe organic farming. Enhancing soil health is the cornerstone of organic farming. A variety of methods are employed, including crop rotation, green manure, cover cropping, application of compost, and mulching.

8. During the Tenth Plan period, the Government of India implemented a new scheme—National Project on Organic Farming—for production, promotion, market development of organic farming in India.

   The main components of the scheme include the following:

   i. Putting in place a system of certification of organic produce
   ii. Capacity building through service providers
   iii. Financial support for commercial production units for production of organic inputs like fruits and vegetable waste compost units, bio-fertilisers production, and hatcheries for vermiculture
   iv. Promotion, extension and market development of organic farming

   These components will be put into action during the 11th Plan.

   Given India's relative scarcity of land, large farmer population and fragmented land-holdings, the benefits of organic farming appear uniquely suited to Indian conditions.

   In Madhya Pradesh, organic farming is being implemented under the guidance of a team of experts comprising scientists,
