74. Mohorovicic discontinuity (Moho) - separates the crust from the mantle, its average depth being about 35 km. A soft asthenosphere (highly viscous, mechanically weak and ductile). It is a part of mantle. Gutenberg Discontinuity - lies between the mantle and the outer core below 2900 km from earth's surface.
75. The correct order of soil erosion process is splash erosion, sheet erosion, rill erosion and gully erosion. Splash occurs when the raindrop hits the surface; explosive impact soil into individual particles. Sheet erosion is the detachment of soil particles by rain drop and their removal down slope by water flowing overland as a sheet in definite channels. Rill erosion refers to the development of small ephemeral concentrated flow paths which function as both sedimentary source and sediment delivery systems for erosion on hill slopes. Sheet erosion removes this top layer by raindrop kill or erosion occurs in lines which are less than 30 cm deep when these rills are deeper than 30 cm forming channels are called as gully erosion. Gully erosion occurs when water flows in narrow channels after heavy rain and melting snow.
76. Both orogenic movements and earthquakes create uplifts of surface lands. Epeirogenic or continent forming movements act along the radius of the earth; therefore, they are also called radial movements. Their direction may be towards (subsidence) or away (uplift) from the center.
77. Plate Tectonics, formation of mid-oceanic ridges, origins of earthquake, formation of fold mountains all can be better understood when studied along with the knowledge of Continental Drift Theory of Wegner and Sea floor spreading theory.
78. The **San Andreas Fault** is a continental transform fault that extends through California. It forms the tectonic boundary between the Pacific Plate and the North American plate, and its motion is right-lateral strike-slip (horizontal). Nazca plate has convergent boundary with South American Plate while it has divergent boundary with Cocos plate and Pacific plate.
