therefore, receives the maximum heat and is called the torrid zone.

2. Temperature falls with increasing latitude (as we move from equator towards poles):
   Because of the spherical (Geoid) shape of the earth and the position of the Sun.
   Because the energy received per unit area decreases from equator to poles.
   Because Equator receives direct sunlight while Poles receive slant or oblique rays of the Sun.
3. Diurnal and annual range of temperatures are highest in the interiors of continents due to the effect of continentality (in continental interiors these will no moderating effect of oceans).
   Diurnal and annual range of temperatures are least in oceans. [high specific heat of water and mixing of water keep the range low].
4. In subtropics clouds are not there or are less in amount, the heat is directly radiated from the Sun due to which there will be higher temperatures in the region. That is the reason why areas of earth experience higher temperatures in the subtropics of the northern hemisphere rather than at the equator.
5. Fall in temperature with the rising of the air parcel is called Adiabatic Temperature Lapse. And the rate at which it happens is called Adiabatic Lapse Rate. This is Positive Adiabatic Lapse Rate as the Temperature is falling. Rising of a parcel of air and associated Positive Adiabatic Lapse Rate is the first step in the formation of Thunderstorms, Tornadoes and Cyclones.
6. A, B, C are correct.
   Air expands when heated and gets compressed when cooled. This results in variations in the atmospheric pressure.
   The differences in atmospheric pressure causes the movement of air from high pressure to low pressure, setting the air in motion. Atmospheric pressure also determines when the air will rise or sink.
   Air in horizontal motion is wind. The wind redistributes the heat and moisture across latitudes, thereby, maintaining a constant temperature for the planet as a whole.
